

Quasi-Monte Carlo methods for Bayesian optimal experimental design problems governed by PDEs

Vesa Kaarnioja (FU Berlin), Claudia Schillings (FU Berlin)

September 7, 2023

Table of contents

Part I: Quasi-Monte Carlo methods

Part II: Bayesian optimal experimental design

Part I: Quasi-Monte Carlo methods

High-dimensional numerical integration

$$\int_{[0,1]^s} f(\mathbf{y}) d\mathbf{y} \approx \sum_{i=1}^n w_i f(\mathbf{t}_i)$$

Figure 1: Tensor product grid, sparse grid, Monte Carlo nodes (not QMC rules)

Figure 2: Sobol' points, lattice rule (examples of QMC rules)

Quasi-Monte Carlo (QMC) methods are a class of *equal weight* cubature rules

$$\int_{[0,1]^s} f(\mathbf{y}) \, d\mathbf{y} \approx \frac{1}{n} \sum_{i=1}^n f(\mathbf{t}_i),$$

where $(\mathbf{t}_i)_{i=1}^n$ is an ensemble of *deterministic* nodes in $[0, 1]^s$.

The nodes $(\mathbf{t}_i)_{i=1}^n$ are NOT random!! Instead, they are *deterministically chosen*.

QMC methods exploit the smoothness and anisotropy of an integrand in order to achieve better-than-Monte Carlo rates.

Lattice rules

Rank-1 lattice rules

$$Q_{s,n}(f) = \frac{1}{n} \sum_{i=1}^n f(\mathbf{t}_i)$$

have the points

$$\mathbf{t}_i = \text{mod} \left(\frac{i\mathbf{z}}{n}, 1 \right), \quad i \in \{1, \dots, n\},$$

where the entire point set is determined by the *generating vector* $\mathbf{z} \in \mathbb{N}^s$, with all components *coprime* to n .

Lattice rule with $\mathbf{z} = (1, 55)$ and $n = 89$
nodes in $[0, 1]^2$

The quality of the lattice rule is determined by the choice of \mathbf{z} .

Randomly shifted lattice rules

Shifted rank-1 lattice rules have points

$$\mathbf{t}_i = \text{mod} \left(\frac{i\mathbf{z}}{n} + \mathbf{\Delta}, 1 \right), \quad i \in \{1, \dots, n\}.$$

$\mathbf{\Delta} \in [0, 1)^s$ is the *shift*

Use a number of random shifts for error estimation.

Lattice rule shifted by $\mathbf{\Delta} = (0.1, 0.3)$.

Let $\mathbf{\Delta}^{(r)}$, $r = 1, \dots, R$, be independent random shifts drawn from $U([0, 1]^s)$ and define

$$Q_{s,n}^{(r)}(f) := \frac{1}{n} \sum_{i=1}^n f(\text{mod}(\mathbf{t}_i + \mathbf{\Delta}^{(r)}, 1)). \quad (\text{QMC rule with 1 random shift})$$

Then

$$\overline{Q}_{s,n}(f) = \frac{1}{R} \sum_{r=1}^R Q_{s,n}^{(r)} f \quad (\text{QMC rule with } R \text{ random shifts})$$

is an unbiased estimator of $I_s(f)$.

Let $f: [0, 1]^s \rightarrow \mathbb{R}$ be sufficiently smooth.

Error bound (one random shift):

$$|I_s(f) - Q_{s,n}^{\Delta}(f)| \leq e_{s,n,\gamma}^{\Delta}(\mathbf{z}) \|f\|_{\gamma}.$$

R.M.S. error bound (shift-averaged):

$$\sqrt{\mathbb{E}_{\Delta}[|I_s(f) - \bar{Q}_{s,n}(f)|^2]} \leq e_{s,n,\gamma}^{\text{sh}}(\mathbf{z}) \|f\|_{\gamma}.$$

We consider weighted Sobolev spaces with dominating mixed smoothness, equipped with norm

$$\|f\|_{\gamma}^2 = \sum_{\mathbf{u} \subseteq \{1:s\}} \frac{1}{\gamma_{\mathbf{u}}} \int_{[0,1]^{|\mathbf{u}|}} \left(\int_{[0,1]^{s-|\mathbf{u}|}} \frac{\partial^{|\mathbf{u}|} f}{\partial \mathbf{y}_{\mathbf{u}}}(\mathbf{y}) d\mathbf{y}_{-\mathbf{u}} \right)^2 d\mathbf{y}_{\mathbf{u}}$$

and (squared) worst case error

$$P(\mathbf{z}) := e_{s,n,\gamma}^{\text{sh}}(\mathbf{z})^2 = \frac{1}{n} \sum_{k=0}^{n-1} \sum_{\emptyset \neq \mathbf{u} \subseteq \{1:s\}} \gamma_{\mathbf{u}} \prod_{j \in \mathbf{u}} \omega\left(\left\{\frac{kz_j}{n}\right\}\right)$$

where $\omega(x) = x^2 - x + \frac{1}{6}$.

CBC algorithm (Sloan, Kuo, Joe 2002)

The idea of the *component-by-component* (CBC) algorithm is to find a good generating vector $\mathbf{z} = (z_1, \dots, z_s)$ by proceeding as follows:

1. Set $z_1 = 1$;
2. With z_1 fixed, choose z_2 to minimize error criterion $P(z_1, z_2)$;
3. With z_1 and z_2 fixed, choose z_3 to minimize error criterion $P(z_1, z_2, z_3)$
- \vdots

Efficient implementation using FFT (QMC4PDE, QMCPy, etc.) if weights have certain structure (e.g., POD weights).

Theorem (CBC error bound)

The generating vector $\mathbf{z} \in \mathbb{N}^s$ constructed by the CBC algorithm, minimizing the squared shift-averaged worst-case error $[e_{s,n,\gamma}^{\text{sh}}(\mathbf{z})]^2$ for the weighted unanchored Sobolev space in each step, satisfies

$$[e_{s,n,\gamma}^{\text{sh}}(\mathbf{z})]^2 \leq \left(\frac{1}{\varphi(n)} \sum_{\emptyset \neq \mathbf{u} \subseteq \{1:s\}} \gamma_{\mathbf{u}}^{\lambda} \left(\frac{2\zeta(2\lambda)}{(2\pi^2)^{\lambda}} \right)^{|\mathbf{u}|} \right)^{1/\lambda} \quad \text{for all } \lambda \in (1/2, 1],$$

where $\zeta(x) := \sum_{k=1}^{\infty} k^{-x}$ denotes the Riemann zeta function for $x > 1$.

Remarks:

- Optimal rate of convergence $\mathcal{O}(n^{-1+\delta})$ in weighted Sobolev spaces, independently of s under an appropriate condition on the weights.
- Cost of algorithm for POD weights is $\mathcal{O}(s n \log n + s^2 n)$ using FFT.

Significance: Suppose that $f \in H_{s,\gamma}$ for all $\gamma = (\gamma_u)_{u \subseteq \{1:s\}}$. Then for any given sequence of weights γ , we can use the CBC algorithm to obtain a generating vector satisfying the error bound

$$\sqrt{\mathbb{E}_{\Delta} |I_s f - Q_{s,n}^{\Delta} f|^2} \leq \left(\frac{1}{\varphi(n)} \sum_{\emptyset \neq u \subseteq \{1:s\}} \gamma_u^{\lambda} \left(\frac{2\zeta(2\lambda)}{(2\pi^2)^{\lambda}} \right)^{|u|} \right)^{1/(2\lambda)} \|f\|_{s,\gamma} \quad (1)$$

for all $\lambda \in (1/2, 1]$. We can use the following strategy:

- For a given integrand f , estimate the norm $\|f\|_{s,\gamma}$.
- Find weights γ which *minimize* the error bound (1).
- Using the optimized weights γ as input, use the CBC algorithm to find a generating vector which *satisfies* the error bound (1).

Part II: Bayesian optimal experimental design

Let $G: \Theta \times \Xi \rightarrow \mathbb{R}^k$ be a forward mapping depending on a true parameter $\theta \in \Theta$ and a design parameter $\xi \in \Xi$.

Measurement model:

$$\mathbf{y} = G(\theta, \xi) + \eta,$$

where $\mathbf{y} \in \mathbb{R}^k$ is the measurement data and $\eta \in \mathbb{R}^k$ is Gaussian noise such that $\eta \sim \mathcal{N}(0, \Gamma)$ with positive definite covariance matrix $\Gamma \in \mathbb{R}^{k \times k}$.

Goal in Bayesian optimal experimental design: Recover the design parameter ξ for the Bayesian inference of θ , which we model as a random variable endowed with prior distribution $\pi(\theta)$.

Example

Suppose we have 9 slots and 4 sensors. Before carrying out the experiment, which 4 slots do we expect to be the most informative for the recovery of the unknown parameter?

→ $\binom{9}{4} = 126$ possible configurations

Left: 9 slots. Right: We have 126 possible ways to place 4 sensors into 9 slots.

How to rank the 126 different possibilities from most informative to least informative?

A measure of the information gain for a given design ξ and data \mathbf{y} is given by the Kullback–Leibler divergence

$$D_{\text{KL}}(\pi(\cdot|\mathbf{y}, \xi) \parallel \pi(\cdot)) := \int_{\Theta} \log \left(\frac{\pi(\boldsymbol{\theta}|\mathbf{y}, \xi)}{\pi(\boldsymbol{\theta})} \right) \pi(\boldsymbol{\theta}|\mathbf{y}, \xi) d\boldsymbol{\theta}. \quad (2)$$

We wish to maximize the expected utility (2) over the design space Ξ with respect to the data \mathbf{y} and model parameters $\boldsymbol{\theta}$:

$$\max_{\xi \in \Xi} \underbrace{\int_{\mathcal{Y}} \int_{\Theta} \log \left(\frac{\pi(\boldsymbol{\theta}|\mathbf{y}, \xi)}{\pi(\boldsymbol{\theta})} \right) \pi(\boldsymbol{\theta}|\mathbf{y}, \xi) \pi(\mathbf{y}|\xi) d\boldsymbol{\theta} d\mathbf{y}}_{=:\text{EIG}},$$

where $\pi(\boldsymbol{\theta}|\mathbf{y}, \xi)$ corresponds to the posterior distribution of the parameter $\boldsymbol{\theta}$ and $\pi(\mathbf{y}|\xi) = \int_{\Theta} \pi(\mathbf{y}|\boldsymbol{\theta}, \xi) \pi(\boldsymbol{\theta}) d\boldsymbol{\theta}$ is the marginal distribution of the data \mathbf{y} .

The posterior is given by Bayes' theorem

$$\pi(\boldsymbol{\theta}|\mathbf{y}, \boldsymbol{\xi}) = \frac{\pi(\mathbf{y}|\boldsymbol{\theta}, \boldsymbol{\xi})\pi(\boldsymbol{\theta})}{\pi(\mathbf{y}|\boldsymbol{\xi})},$$

which means that the expected utility can be written as

$$\begin{aligned}\text{EIG} &= \int_{\mathbf{Y}} \int_{\boldsymbol{\Theta}} \log \left(\frac{\pi(\boldsymbol{\theta}|\mathbf{y}, \boldsymbol{\xi})}{\pi(\boldsymbol{\theta})} \right) \pi(\boldsymbol{\theta}|\mathbf{y}, \boldsymbol{\xi}) \, \mathrm{d}\boldsymbol{\theta} \, \pi(\mathbf{y}|\boldsymbol{\xi}) \, \mathrm{d}\mathbf{y} \\ &= \int_{\boldsymbol{\Theta}} \left[\int_{\mathbf{Y}} \log \left(\frac{\pi(\mathbf{y}|\boldsymbol{\theta}, \boldsymbol{\xi})}{\pi(\mathbf{y}|\boldsymbol{\xi})} \right) \pi(\mathbf{y}|\boldsymbol{\theta}, \boldsymbol{\xi}) \, \mathrm{d}\mathbf{y} \right] \pi(\boldsymbol{\theta}) \, \mathrm{d}\boldsymbol{\theta}.\end{aligned}$$

Approaches taken in the literature:

- Double-loop Monte Carlo (Beck, Mansour, Espath, Long, Tempone)
- MCLA (Beck, Mansour, Espath, Long, Tempone)
- DLMCIS (Beck, Mansour, Espath, Long, Tempone)

Let us assume the following:

A1 The forward model $\mathbf{y} = G(\boldsymbol{\theta}, \boldsymbol{\xi}) + \boldsymbol{\eta}$ satisfies

$$\|\partial_{\boldsymbol{\theta}}^{\boldsymbol{\nu}} G(\boldsymbol{\theta}, \boldsymbol{\xi})\| \leq C_0 |\boldsymbol{\nu}|! \mathbf{b}^{\boldsymbol{\nu}},$$

where $\mathbf{b} := (b_j)_{j \geq 1} \in \ell^p$ are nonnegative real numbers for some $p \in (0, 1)$ and $C_0 \geq 1$ is independent of $\boldsymbol{\xi} \in \Xi$.

A2 $\Theta = [-\frac{1}{2}, \frac{1}{2}]^s$ and $\pi(\boldsymbol{\theta}) = 1$ for $\boldsymbol{\theta} \in \Theta$ and 0 otherwise.

A3 The noise covariance is $\Gamma = \sigma^2 I_k$, $0 < \sigma \leq 1$.

Model problem: Let $D \subset \mathbb{R}^d$, $d \in \{1, 2, 3\}$, be a nonempty, bounded, and convex Lipschitz domain and $z \in L^2(D)$. For each $\boldsymbol{\theta} \in \Theta$, there exists a strong solution $u(\cdot, \boldsymbol{\theta}) \in H^2(D) \cap H_0^1(D)$ to

$$\begin{cases} -\nabla \cdot (a(\mathbf{x}, \boldsymbol{\theta}) \nabla u(\mathbf{x}, \boldsymbol{\theta})) = z(\mathbf{x}), & \mathbf{x} \in D, \boldsymbol{\theta} \in \Theta, \\ u(\mathbf{x}, \boldsymbol{\theta}) = 0, & \mathbf{x} \in \partial D, \boldsymbol{\theta} \in \Theta, \end{cases}$$

where we assume that $\boldsymbol{\theta} = (\theta_j)_{j \geq 1}$ i.i.d. uniformly distributed in $[-1/2, 1/2]$,

$$a(\mathbf{x}, \boldsymbol{\theta}) = a_0(\mathbf{x}) + \sum_{j \geq 1} \theta_j \psi_j(\mathbf{x}), \quad \mathbf{x} \in D, \boldsymbol{\theta} \in [-1/2, 1/2]^{\mathbb{N}},$$

with $a_0 \in W^{1,\infty}(D)$ and $\psi_j \in W^{1,\infty}(D)$, $j \geq 1$, such that $\sum_{j \geq 1} \|\psi_j\|_{W^{1,\infty}(D)} < \infty$, $0 < a_{\min} \leq a(\mathbf{x}, \boldsymbol{\theta}) \leq a_{\max} < \infty$ for all $\mathbf{x} \in D$, $\boldsymbol{\theta} \in [-1/2, 1/2]^{\mathbb{N}}$, and $b_j := \|\psi_j\|_{L^\infty(D)} / a_{\min}$.

Then $G(\boldsymbol{\theta}, \boldsymbol{\xi}) := (u(\mathbf{x}, \boldsymbol{\theta}))_{\mathbf{x} \in \boldsymbol{\xi}}$, where $\boldsymbol{\xi} = \{\mathbf{x}_1, \dots, \mathbf{x}_k\} \subset D$, satisfies A1.

If $\boldsymbol{\theta} \perp \boldsymbol{\eta}$, then the likelihood is given by

$$\pi(\mathbf{y}|\boldsymbol{\theta}, \boldsymbol{\xi}) = C e^{-\frac{1}{2\sigma^2} \|\mathbf{y} - G(\boldsymbol{\theta}, \boldsymbol{\xi})\|^2}, \quad C = \frac{1}{(2\pi\sigma^2)^{k/2}}.$$

Under these conditions, it is easy to see that

$$\begin{aligned} \text{EIG} &= \int_Y \int_{\Theta} \log \left(\frac{\pi(\mathbf{y}|\boldsymbol{\theta}, \boldsymbol{\xi})}{\pi(\mathbf{y}|\boldsymbol{\xi})} \right) \pi(\mathbf{y}|\boldsymbol{\theta}, \boldsymbol{\xi}) \pi(\boldsymbol{\theta}) \, d\boldsymbol{\theta} \, d\mathbf{y} \\ &= \log C - 1 - \int_Y \log \left(\int_{\Theta} C e^{-\frac{1}{2\sigma^2} \|\mathbf{y} - G(\boldsymbol{\theta}, \boldsymbol{\xi})\|^2} \, d\boldsymbol{\theta} \right) \int_{\Theta} C e^{-\frac{1}{2\sigma^2} \|\mathbf{y} - G(\boldsymbol{\theta}, \boldsymbol{\xi})\|^2} \, d\boldsymbol{\theta} \, d\mathbf{y}. \end{aligned}$$

Observations:

- The **inner integral** can be approximated *independently* of the dimension s using QMC.
- In general, the data dimension k affects the QMC cubature error bound of the **outer integral**.
- How to efficiently approximate the nested integrals?

Consider

$$\int_{\mathbf{y}} \log \left(\int_{\Theta} C e^{-\frac{1}{2\sigma^2} \|\mathbf{y} - G(\boldsymbol{\theta}, \boldsymbol{\xi})\|^2} d\boldsymbol{\theta} \right) \int_{\Theta} C e^{-\frac{1}{2\sigma^2} \|\mathbf{y} - G(\boldsymbol{\theta}, \boldsymbol{\xi})\|^2} d\boldsymbol{\theta} d\mathbf{y}.$$

- Parametric regularity of the integrand in

$$\int_{\Theta} C e^{-\frac{1}{2\sigma^2} \|\mathbf{y} - G(\boldsymbol{\theta}, \boldsymbol{\xi})\|^2} d\boldsymbol{\theta}$$

is well-understood (as long as the parametric regularity of G can be quantified); straightforward modification of Herrmann–Keller–Schwab (2021).

- More generally, in many applications of UQ, we are interested in parametric integrals of quantities of the general form

$$f(G(\boldsymbol{\theta}, \cdot)), \quad (3)$$

where $f: \mathbb{R}^k \rightarrow \mathbb{R}$ is a (somewhat) smooth nonlinear quantity of interest[†], and

$$\|\partial_{\boldsymbol{\theta}}^{\boldsymbol{\nu}} G(\boldsymbol{\theta}, \cdot)\| \leq C_0 |\boldsymbol{\nu}|! \mathbf{b}^{\boldsymbol{\nu}}.$$

What can be said about the parametric regularity of (3)?

[†]E.g., $f(\mathbf{x}) = \|\mathbf{y} - \mathbf{x}\|^2$ or $f(\mathbf{x}) = e^{-\frac{1}{2\sigma^2} \|\mathbf{y} - \mathbf{x}\|^2}$.

Faà di Bruno's formula:

$$\partial_{\theta}^{\nu} f(G(\theta, \cdot)) = \sum_{\substack{1 \leq |\lambda| \leq |\nu| \\ \lambda \in \mathbb{N}_0^k}} \partial_x^{\lambda} f(x) \Big|_{x=G(\theta, \cdot)} \kappa_{\nu, \lambda}(\theta), \quad \nu \neq \mathbf{0},$$

where the sequence $(\kappa_{\nu, \lambda})$ depends only on G via

$$\kappa_{\nu, \mathbf{0}} \equiv \delta_{\nu, \mathbf{0}},$$

$$\kappa_{\nu, \lambda} \equiv 0 \quad \text{if } |\nu| < |\lambda| \text{ or } \lambda \not\geq \mathbf{0} \text{ (i.e., if } \lambda \text{ contains negative entries),}$$

$$\kappa_{\nu + e_j, \lambda}(\theta) = \sum_{\ell \in \text{supp}(\lambda)} \sum_{\mathbf{0} \leq \mathbf{m} \leq \nu} \binom{\nu}{\mathbf{m}} \partial^{\mathbf{m} + e_j} [G(\theta, \cdot)]_{\ell} \kappa_{\nu - \mathbf{m}, \lambda - e_{\ell}}(\theta) \quad \text{otherwise.}$$

Since $\|\partial_{\theta}^{\nu} G(\theta, \cdot)\| \leq C_0 |\nu|! \mathbf{b}^{\nu}$, we obtain the following *uniform* bound.

Lemma

For all $1 \leq |\lambda| \leq |\nu|$, there holds

$$|\kappa_{\nu, \lambda}(\theta)| \leq C_0^{|\lambda|} \frac{|\nu|! (|\nu| - 1)!}{\lambda! (|\nu| - |\lambda|)! (|\lambda| - 1)!} \mathbf{b}^{\nu}.$$

Proof.

By induction w.r.t. the order of the multi-index ν .

□

For the present problem, we obtain

$$\begin{aligned}
& \left| \partial_{\boldsymbol{\theta}}^{\boldsymbol{\nu}} e^{-\frac{1}{2\sigma^2} \|\mathbf{y} - G(\boldsymbol{\theta}, \cdot)\|^2} \right| \\
& \leq \left(\frac{C_0}{\sigma} \right)^{|\boldsymbol{\nu}|} \sum_{\substack{1 \leq |\boldsymbol{\lambda}| \leq |\boldsymbol{\nu}| \\ \boldsymbol{\lambda} \in \mathbb{N}_0^k}} \left| \partial_{\mathbf{x}}^{\boldsymbol{\lambda}} e^{-\mathbf{x}^T \mathbf{x} / 2} \right|_{\mathbf{x} = \sigma^{-1}(\mathbf{y} - G(\boldsymbol{\theta}, \cdot))} \frac{|\boldsymbol{\nu}|! (|\boldsymbol{\nu}| - 1)!}{\boldsymbol{\lambda}|! (|\boldsymbol{\nu}| - |\boldsymbol{\lambda}|)! (|\boldsymbol{\lambda}| - 1)!} \mathbf{b}^{\boldsymbol{\nu}}.
\end{aligned}$$

Cramér's inequality:

$$\left| \frac{d^{\boldsymbol{\lambda}}}{d\mathbf{x}^{\boldsymbol{\lambda}}} e^{-\mathbf{x}^T \mathbf{x} / 2} \right| \leq 1.1 \sqrt{\boldsymbol{\lambda}}! \quad \Rightarrow \quad \left| \partial_{\mathbf{x}}^{\boldsymbol{\lambda}} e^{-\mathbf{x}^T \mathbf{x} / 2} \right| \leq 1.1^k \sqrt{\boldsymbol{\lambda}}!$$

and thus

$$\begin{aligned}
& \left| \partial_{\boldsymbol{\theta}}^{\boldsymbol{\nu}} e^{-\frac{1}{2\sigma^2} \|\mathbf{y} - G(\boldsymbol{\theta}, \cdot)\|^2} \right| \\
& \leq 1.1^k \left(\frac{C_0}{\sigma} \right)^{|\boldsymbol{\nu}|} \mathbf{b}^{\boldsymbol{\nu}} |\boldsymbol{\nu}|! (|\boldsymbol{\nu}| - 1)! \sum_{\substack{1 \leq |\boldsymbol{\lambda}| \leq |\boldsymbol{\nu}| \\ \boldsymbol{\lambda} \in \mathbb{N}_0^k}} \frac{\sqrt{\boldsymbol{\lambda}}!}{\boldsymbol{\lambda}|! (|\boldsymbol{\nu}| - |\boldsymbol{\lambda}|)! (|\boldsymbol{\lambda}| - 1)!}.
\end{aligned}$$

It remains to estimate the multi-index sum, but fortunately this is not too difficult:

$$\begin{aligned}
\sum_{\substack{1 \leq |\lambda| \leq |\nu| \\ \lambda \in \mathbb{N}_0^k}} \frac{\sqrt{\lambda!}}{\lambda!(|\nu| - |\lambda|)!(|\lambda| - 1)!} &= \sum_{\ell=1}^{|\nu|} \frac{1}{(|\nu| - \ell)!(\ell - 1)!} \sum_{\substack{\lambda \in \mathbb{N}_0^k \\ |\lambda| = \ell}} \frac{1}{\sqrt{\lambda!}} \\
&\leq \sum_{\ell=1}^{|\nu|} \frac{1}{(|\nu| - \ell)!(\ell - 1)!} \left(\sum_{\lambda=0}^{\infty} \frac{1}{\sqrt{\lambda!}} \right)^k \\
&\leq 3.47^k \cdot \frac{2^{|\nu|-1}}{(|\nu| - 1)!},
\end{aligned}$$

where we made use of $\sum_{\lambda=0}^{\infty} \frac{1}{\sqrt{\lambda!}} = 3.469506 \dots$ and the summation identity $\sum_{\ell=1}^{\nu} \frac{1}{(\nu-\ell)!(\ell-1)!} = \frac{2^{\nu-1}}{(\nu-1)!}$.

Summa summarum:

Lemma

For all $\nu \neq \mathbf{0}$, there holds

$$|\partial_{\theta}^{\nu} e^{-\frac{1}{2\sigma^2} \|\mathbf{y} - G(\theta, \cdot)\|^2}| \leq 3.82^k \cdot C_0^{|\nu|} 2^{|\nu|-1} \sigma^{-|\nu|} |\nu|! \mathbf{b}^{\nu}.$$

Decomposing the high-dimensional integral

Suppose that $Y = \mathbb{R}^k$. Then

$$\begin{aligned}
 & \int_{\mathbb{R}^k} \log \left(\int_{\Theta} C e^{-\frac{1}{2\sigma^2} \|\mathbf{y} - G(\boldsymbol{\theta}, \boldsymbol{\xi})\|^2} d\boldsymbol{\theta} \right) \int_{\Theta} C e^{-\frac{1}{2\sigma^2} \|\mathbf{y} - G(\tilde{\boldsymbol{\theta}}, \boldsymbol{\xi})\|^2} d\tilde{\boldsymbol{\theta}} d\mathbf{y} \\
 &= \int_{[-K, K]^k} \log \left(\int_{\Theta} C_{k, \sigma} e^{-\frac{1}{2\sigma^2} \|\mathbf{y} - G(\boldsymbol{\theta}, \boldsymbol{\xi})\|^2} d\boldsymbol{\theta} \right) \int_{\Theta} C e^{-\frac{1}{2\sigma^2} \|\mathbf{y} - G(\tilde{\boldsymbol{\theta}}, \boldsymbol{\xi})\|^2} d\tilde{\boldsymbol{\theta}} d\mathbf{y} \\
 &+ \int_{\mathbb{R}^k \setminus [-K, K]^k} \log \left(\int_{\Theta} C e^{-\frac{1}{2\sigma^2} \|\mathbf{y} - G(\boldsymbol{\theta}, \boldsymbol{\xi})\|^2} d\boldsymbol{\theta} \right) \int_{\Theta} C e^{-\frac{1}{2\sigma^2} \|\mathbf{y} - G(\tilde{\boldsymbol{\theta}}, \boldsymbol{\xi})\|^2} d\tilde{\boldsymbol{\theta}} d\mathbf{y} \\
 &=: \mathcal{I}_K + \tilde{\mathcal{I}}_K.
 \end{aligned}$$

For $K \gg 1$, there holds

$$\begin{aligned}
 |\tilde{\mathcal{I}}_K| &\leq C^{1/2} e^{\frac{\|\bar{G}\|^2}{4\sigma^2}} (4\pi\sigma^2)^{k/2} \\
 &- C^{1/2} e^{\frac{\|\bar{G}\|^2}{4\sigma^2}} (\pi\sigma^2)^{k/2} \prod_{j=1}^k \left(\operatorname{erf} \left(\frac{\bar{G}_j + K}{2\sigma} \right) - \operatorname{erf} \left(\frac{\bar{G}_j - K}{2\sigma} \right) \right),
 \end{aligned}$$

where $\bar{G} := (\bar{G}_j)_{j=1}^k := G(\boldsymbol{\theta}^*, \boldsymbol{\xi}^*)$, $(\boldsymbol{\theta}^*, \boldsymbol{\xi}^*) := \arg \max_{(\boldsymbol{\theta}, \boldsymbol{\xi}) \in (\Theta, \Xi)} \|G(\boldsymbol{\theta}, \boldsymbol{\xi})\|$.

$$\int_{[-K,K]^k} \log \left(\int_{\Theta} C e^{-\frac{1}{2\sigma^2} \|\mathbf{y} - G(\boldsymbol{\theta}, \boldsymbol{\xi})\|^2} d\boldsymbol{\theta} \right) \int_{\Theta} C e^{-\frac{1}{2\sigma^2} \|\mathbf{y} - G(\boldsymbol{\theta}, \boldsymbol{\xi})\|^2} d\boldsymbol{\theta} d\mathbf{y}$$

QMC weights for the **inner integral**:

$$\gamma_u = \left(|u|! \prod_{j \in u} \frac{\beta_j}{\sqrt{2\zeta(2\lambda)/(2\pi^2)^\lambda}} \right)^{\frac{2}{1+\lambda}}, \quad \lambda = \begin{cases} \frac{p}{2-p} & \text{if } p \in (2/3, 1), \\ \frac{1}{2-2\delta} & \text{if } p \in (0, 2/3], \end{cases}$$

with $\beta_j := \frac{2C_0}{\sigma} b_j$, $j \in \{1, \dots, s\}$, and $\delta > 0$ arbitrary, yields the QMC convergence rate

$$\mathcal{O}(\varphi(n)^{\max\{-1/p+1/2, -1+\delta\}})$$

independently of the dimension s with $\varphi(n)$ denoting the Euler totient function.

$$\int_{[-K,K]^k} \log \left(\int_{\Theta} C e^{-\frac{1}{2\sigma^2} \|\mathbf{y}-G(\boldsymbol{\theta},\boldsymbol{\xi})\|^2} d\boldsymbol{\theta} \right) \int_{\Theta} C e^{-\frac{1}{2\sigma^2} \|\mathbf{y}-G(\boldsymbol{\theta},\boldsymbol{\xi})\|^2} d\boldsymbol{\theta} d\mathbf{y}$$

QMC weights for the **outer integral**:

$$\tilde{\gamma}_u = \left(|u|! \prod_{j \in u} \frac{1.1^k k \sigma^{-1} e^{\frac{1}{2\sigma^2} (kK^2 + 2\sqrt{k}KC + C^2)}}{\log(2) \sqrt{2\zeta(2\tilde{\lambda})/(2\pi^2)^{\tilde{\lambda}}}} \right)^{\frac{2}{1+\tilde{\lambda}}}, \quad \tilde{\lambda} = \frac{1}{2-2\tilde{\delta}},$$

with $\tilde{\delta} > 0$ arbitrary, yields the QMC convergence rate

$$\mathcal{O}(\varphi(n)^{-1+\tilde{\delta}})$$

with $\varphi(n)$ denoting the Euler totient function. Note that the implied coefficient **depends on k** .

The nested integral

Goal of computation:

$$\mathcal{I}_K(f) = \int_{Y_K} g\left(\int_{\Theta} f(\boldsymbol{\theta}, \mathbf{y}, \boldsymbol{\xi}) d\boldsymbol{\theta}\right) d\mathbf{y},$$

where $g(x) := x \log x$, $Y_K = [-K, K]^k$, and $f(\boldsymbol{\theta}, \mathbf{y}, \boldsymbol{\xi}) := C e^{-\frac{1}{2\sigma^2} \|\mathbf{y} - G(\boldsymbol{\theta}, \boldsymbol{\xi})\|^2}$.

Define a hierarchy of QMC cubature operators for the **outer integral**,
i.e.,

$$I^{(1)}F := \int_{Y_K} F(\mathbf{y}) d\mathbf{y} \approx 2^{-\ell} \sum_{k=1}^{2^\ell} F(\mathbf{y}_k^{(\ell)}) =: Q_\ell^{(1)}F, \ell = \ell_0^{(1)}, \ell_0^{(1)}+1, \ell_0^{(1)}+2, \dots,$$

for a given function $F \in \tilde{H}_{k, \tilde{\gamma}}$, and likewise for the **inner integral**

$$I^{(2)}F := \int_{\Theta} F(\boldsymbol{\theta}) d\boldsymbol{\theta} \approx 2^{-\ell} \sum_{k=1}^{2^\ell} F(\boldsymbol{\theta}_k^{(\ell)}) =: Q_\ell^{(2)}F, \ell = \ell_0^{(2)}, \ell_0^{(2)}+1, \ell_0^{(2)}+2, \dots,$$

for a given function $F \in H_{s, \gamma}$.

Why full tensor product cubature is a bad idea

Approximating the integral

$$\mathcal{I}_K(f) = \int_{Y_K} g \left(\int_{\Theta} f(\boldsymbol{\theta}, \mathbf{y}, \boldsymbol{\xi}) \, \mathrm{d}\boldsymbol{\theta} \right) \mathrm{d}\mathbf{y},$$

by

$$\mathcal{I}_K(f) \approx Q_{\ell}^{(1)} g(Q_{\ell}^{(2)} f) \tag{4}$$

is inefficient. A hand-wavy argument would be as follows:

- Suppose that we have the approximation rates (recall $n = 2^{\ell}$)

$$|I^{(1)}F - Q_{\ell}^{(1)}F| \asymp n^{-\alpha} \quad \text{and} \quad |I^{(2)}F - Q_{\ell}^{(2)}F| \asymp n^{-\alpha}.$$

- Evaluating (4) takes $N = n^2$ function calls, but the cubature accuracy will not be better than $\mathcal{O}(n^{-\alpha}) = \mathcal{O}(N^{-\alpha/2})$
→ the convergence rate is effectively halved! (“Curse of dimensionality”)

Sparse tensor product cubature in the vein of Gilch, Griebel, Oettershagen (2022)

Define the difference cubature operator corresponding to the **outer integral**

$$\Delta_{\ell}^{(1)} F := \begin{cases} Q_{\ell}^{(1)} F - Q_{\ell-1}^{(1)} F & \text{if } \ell \geq 1, \\ Q_0^{(1)} F & \text{if } \ell = 0, \end{cases}$$

as well as the *generalized* difference cubature operators corresponding to the **inner integral**

$$\Delta_{\ell}^{(2)} F := \begin{cases} g(Q_{\ell}^{(2)} F) - g(Q_{\ell-1}^{(2)} F) & \text{if } \ell \geq 1, \\ g(Q_0^{(2)} F) & \text{if } \ell = 0. \end{cases}$$

Generalized sparse grid cubature operator:

$$\mathcal{Q}_{L,\varsigma}(f) := \sum_{\varsigma \ell_1 + \frac{\ell_2}{\varsigma} \leq L} \Delta_{\ell_1}^{(1)} \Delta_{\ell_2}^{(2)}(f) = \sum_{\ell_1=0}^{L/\varsigma} \Delta_{\ell_1}^{(1)} g(Q_{\varsigma L - \varsigma^2 \ell_1}^{(2)} f).$$

Sparse tensor product cubature

$$\mathcal{Q}_{L,\varsigma}(f) := \sum_{\varsigma \ell_1 + \frac{\ell_2}{\varsigma} \leq L} \Delta_{\ell_1}^{(1)} \Delta_{\ell_2}^{(2)}(f) = \sum_{\ell_1=0}^{L/\varsigma} \Delta_{\ell_1}^{(1)} g(Q_{\varsigma L - \varsigma^2 \ell_1}^{(2)} f).$$

$$\begin{aligned} \|\mathcal{I}_K(f) - \mathcal{Q}_{L,\varsigma}(f)\|_{\Delta} &:= \sqrt{\mathbb{E}_{\Delta}[\|\mathcal{I}_K(f) - \mathcal{Q}_{L,\varsigma}(f)\|^2]} \\ &\leq \|(I^{(1)} - Q_{L/\varsigma}^{(1)})g(I^{(2)}f)\|_{\Delta} \\ &\quad + \left\| \sum_{\ell_1=0}^{L/\varsigma} \Delta_{\ell_1}^{(1)} (I^{(2)}f - Q_{\varsigma L - \varsigma^2 \ell_1}^{(2)} f) \log(I^{(2)}f) \right\|_{\Delta} \\ &\quad + \left\| \sum_{\ell_1=0}^{L/\varsigma} \Delta_{\ell_1}^{(1)} \left(\frac{Q_{\varsigma L - \varsigma^2 \ell_1}^{(2)} f - I^{(2)}f}{Q_{\varsigma L - \varsigma^2 \ell_1}^{(2)} f} \right) Q_{\varsigma L - \varsigma^2 \ell_1}^{(2)} f \right\|_{\Delta} \\ &\quad + \left\| \sum_{\ell_1=0}^{L/\varsigma} \Delta_{\ell_1}^{(1)} \left(\log \left(\frac{I^{(2)}f}{Q_{\varsigma L - \varsigma^2 \ell_1}^{(2)} f} \right) - \left(\frac{I^{(2)}f}{Q_{\varsigma L - \varsigma^2 \ell_1}^{(2)} f} - 1 \right) \right) Q_{\varsigma L - \varsigma^2 \ell_1}^{(2)} f \right\|_{\Delta}. \end{aligned}$$

Sparse tensor product cubature

$$\mathcal{Q}_{L,\varsigma}(f) := \sum_{\varsigma\ell_1 + \frac{\ell_2}{\varsigma} \leq L} \Delta_{\ell_1}^{(1)} \Delta_{\ell_2}^{(2)}(f) = \sum_{\ell_1=0}^{L/\varsigma} \Delta_{\ell_1}^{(1)} g(Q_{\varsigma L - \varsigma^2 \ell_1}^{(2)} f).$$

Sparse grid error: Our **inner** and **outer** QMC cubatures have essentially linear convergence rates, i.e.,

$$|I^{(1)}f - Q_\ell^{(1)}f| \lesssim 2^{-(1-\delta)\ell} \quad \text{and} \quad |I^{(2)}f - Q_\ell^{(2)}f| \lesssim 2^{-(1-\delta)\ell}.$$

For an *isotropic* ($\varsigma = 1$) sparse tensor product cubature operator, we obtain

$$\|\mathcal{I}_K(f) - \mathcal{Q}_{L,\varsigma}(f)\|_{\Delta} \lesssim 2^{-(1-\delta)L}(L+1)$$

under some additional technical assumptions.

Let $D = (0, 1)^2$. We consider the elliptic PDE

$$\begin{cases} -\nabla \cdot (a(\mathbf{x}, \boldsymbol{\theta}) \nabla u(\mathbf{x}, \boldsymbol{\theta})) = x_1, & \mathbf{x} \in D, \boldsymbol{\theta} \in [-1/2, 1/2]^{100}, \\ u(\cdot, \boldsymbol{\theta})|_{\partial D} = 0, & \boldsymbol{\theta} \in [-1/2, 1/2]^{100}, \end{cases}$$

equipped with the parametric diffusion coefficient

$$a(\mathbf{x}, \boldsymbol{\theta}) = 2 + 0.1 \sum_{j=1}^{100} j^{-2} \theta_j \sin(\pi j x_1) \sin(\pi j x_2), \boldsymbol{\theta} \in [-1/2, 1/2]^{100}.$$

Numerical experiment

The goal is to find a design ξ^* from the set

$$\Xi = \{(\mathbf{x}_1, \mathbf{x}_2, \mathbf{x}_3, \mathbf{x}_4) \in \Upsilon^4 \mid \mathbf{x}_i \neq \mathbf{x}_j \text{ for } i \neq j\},$$

where

$$\begin{aligned} \Upsilon = \{ & (0.25, 0.25), (0.25, 0.50), (0.25, 0.75), \\ & (0.50, 0.25), (0.50, 0.50), (0.50, 0.75), \\ & (0.75, 0.25), (0.75, 0.50), (0.75, 0.75) \}, \end{aligned}$$

maximizing the expected information gain subject to the observation operator

$$G(\boldsymbol{\theta}, \boldsymbol{\xi}) = (u(\mathbf{x}, \boldsymbol{\theta}))_{\mathbf{x} \in \boldsymbol{\xi}}, \quad \boldsymbol{\theta} \in [-1/2, 1/2]^{100}, \quad \boldsymbol{\xi} \in \Xi.$$

Numerical experiment

Full Tensor Product cubature

Sparse Tensor Product cubature

Left: Full tensor product (FTP) cubature of the nested integral subject to affine and uniform parameterization of the input random field. Right: Sparse tensor product (STP) cubature of the nested integral subject to affine and uniform parameterization of the input random field.

Numerical experiment

The value of the objective function using the full tensor product (FTP) scheme for an increasing number of cubature points (left) and the optimal design corresponding to the cubature rule with the largest number of points (right).

Numerical experiment

The value of the objective function using the sparse tensor product (STP) scheme for an increasing number of cubature points (left) and the optimal design corresponding to the cubature rule with the largest number of points (right).

Conclusions and outlook

- QMC for DOE: sparse approach can recover almost the optimal rate.
- Related QMC analysis for PDE-constrained optimal control under uncertainty (including also the optimization process):
